ABSTRACT

Background: Gall stone precipitation is multifactorial in nature. Nowadays, gallbladder disease is a frequent problem in developed countries including India, representing a major health problem. The present study was planned to study the epidemiology of gall stone disease in the region of Madhya Pradesh, India.

Methods: A retrospective cohort of patients seeking surgical care for their gall stone disease during past one year at Sukhsagar Medical College, Jabalpur, Madhya Pradesh, India during formed the study population. Study tools were records of the patients such as information from MRD department and records from histopathological section.

Results: Majority (26.6%) of cases was in the age group of 51-60 years followed by 21.6% cases in the age group of 41-50 years. Sex wise 63.3% were females. Most (71.7%) patients presented with the complaints of pain in the region of hypochondrial region followed by nausea in 46.6%. Jaundice was the least common presenting feature shown by 6.6% patients. As per gross morphology, majority of cases (44) had pigmented stones. As per biochemical analysis, majority of cases (33) had mixed type of stones. The gall stones size varied from 0.2 cm to 2.2 cm in diameter. The weight of gall stones ranged from 0.34 gm to 4.9 gm.

Conclusions: Cholelithiasis is more common in the age group of 41-60 years with female predominance. Non-vegetarians are at risk for cholelithiasis compared to vegetarians. Hypochondrial pain is most common manifestation. Chronic cholecystitis was the most common histopathological diagnosis. Mixed type stones were common variety.

INTRODUCTION

Diseases of the gallbladder are common and costly. Gallstone disease is a chronic recurrent hepatobiliary disease, the basis for which is the impaired metabolism of cholesterol, bilirubin and bile acids, which is characterized by the formation of gallstones in the hepatic bile duct, common bile duct, or gallbladder.1 Gallstone disease remains one of the major causes of abdominal morbidity and mortality through the world.2 Nowadays, gallbladder disease is a frequent problem in developed countries including India, representing a major health problem.3 Gallstone disease and cardiovascular disease, common diseases world-wide, are strongly associated and have
Data of 60 patients was analyzed in this study. Majority (n = 16, 26.6%) of cases were in the age group of 51-60 years followed by 21.6% cases in the age group of 41-50 years (Table 1). Cholelithiasis was more common among non-vegetarians.

*Multiple responses permitted

The stones are divided into 3 groups depending upon their color, varied from yellow and white stones identified as cholesterol stones, dark brown and black as pigment stones and brownish yellow or green as mixed stones.

As per gross morphology, majority of cases (44) had pigmented stones. On the other hand, as per biochemical analysis, majority of cases (33) had mixed type of stones.
(Table 3) The gall stones size varied from 0.2 cm to 2.2 cm in diameter. The weight of gall stones ranged from 0.34 gm to 4.9 gm. There were 45 cases of chronic cholecystitis, the highest incidence of these being in the age group 51-60 years. 6 patients had acute cholecystitis. Other lesions noted were granulomatous cholecystitis, empyema and carcinoma— one in each group. Eosinophilic cholecystitis was noted in 5 patients. On gross examination of gallbladder, outer surface was found congested in 4 patients, increased wall thickness in 37 patients and polyp in 1 patient.

DISCUSSION

The prevalence was more common in Northern Indians than Southern Indians followed by Maharashtra particularly form coastal region. Incidence in India partially attributed to widespread use of ultrasonography (USG) in the last two decades but changing socio-economic structure and changes in various other epidemiological factors including diet may also be responsible.

The stones form due to imbalance or change in the composition of bile. The first factor that predisposes to stone formation is how often and how well the gallbladder contracts; incomplete and infrequent emptying of the gallbladder may cause the bile to become over-concentrated and contribute to gallstone formation. The second important factor is the presence of proteins in the liver and bile that either promote or inhibit cholesterol crystallization into gallstones. Increased levels of the hormone estrogen as a result of pregnancy, hormone therapy, or the use of birth control pills, may increase cholesterol levels in bile and also decrease gallbladder movement, resulting in gallstone formation. Other factors are parity, smoking, alcohol, diabetes and overweight.

In this study we observed that majority (n = 16, 26.6%) of cases were in the age group of 51 - 60 years followed by 21.6% cases in the age group of 41 - 50 years. Maskey CP et al found that the commonest age group for cholelithiasis was below 30 years comprising 37.5%.

In this study we observed that sex wise out of 60, 38 (63.3%) were females and rest were males. A study carried out by Sharma showed that 30% were male and 70% were female10 and Thamil S et al. showed 20.5% males and 79.5% females were patients of cholelithiasis.11 The female gender has a most compelling association with gallstone disease, especially during the fertile years. Women are almost twice as likely as men to form stones; the gap narrows following menopause after which men begin to catch up.12 The underlying mechanism is female sex hormones; parity, oral contraceptive use and estrogen replacement therapy are established risk factors for cholesterol gallstone formation.13 Female sex hormones adversely influence hepatic bile secretion and gallbladder function. Estrogens increase cholesterol secretion and diminish bile salt secretion, while progestins act by reducing bile salt secretion and impairing gallbladder emptying leading to stasis.13

In this study, as per gross morphology, majority of cases (44) had pigmented stones. On the other hand, as per biochemical analysis, majority of cases (33) had mixed type of stones. While a study done in Haryana by Chandran et al. showed 26%, 38% and 36%, respectively.13 Mixed and pigment stones are common in northern India.

We observed that most (43, 71.7%) patients presented with the complaints of pain in the region of hypochondrial region followed by nausea in 46.6%. Jaundice was the least common presenting feature shown by 6.6% patients. Similar results were observed by Sharma et al.14 Vomiting was spontaneous and occurred mostly during the attacks of pain this was also seen by Ganey et al.15

Numerous studies that have assessed the role of diet as a potential risk factor for gallstone formation, including energy intake, cholesterol, fatty acids, fiber, carbohydrates, vitamins and minerals, and alcohol intake. Recent discoveries of the role of orphan nuclear receptors in the regulation of fatty acid and hepatic cholesterol metabolism and excretion open new perspectives for a better understanding of the role of dietary constituents on cholesterol gallstone formation.16

CONCLUSION

On the basis of findings of this study it can be concluded that cholelithiasis is more common in the age group of...
41-60 years with female predominance. Non-vegetarians are at risk for cholelithiasis compared to vegetarians. Hypochondrial pain is most common manifestation. Chronic cholecystitis was the most common histopathological diagnosis. Mixed type stones were common variety.
