INTRODUCTION

Choledochal cysts are a rare congenital cystic dilation of the biliary tract, first described by Vater and Ezler in 1723. They present primarily in female infants and young children and are more prevalent in East Asian populations. Although benign, choledochal cysts can be associated with serious complications including malignant transformation, cholangitis, pancreatitis, and cholelithiasis.1,2 Hence, complete surgical excision of the choledochal cyst and enterobiliary reconstruction has been recommended as the standard treatment.

Choledochal cyst excision and biliary enteric reconstruction constitute the best therapy for choledochal cyst.3 Comparing with open procedure, laparoscopic procedure has been proven to have shorter hospital stay and lower morbidity of anastomotic stenosis, bile leakage, intrahepatic stone formation, cholangitis, pancreatic leak, intestinal obstruction, and re-operation.4,5
Thus, as a safe, efficacious, and minimally invasive procedure, laparoscopic cyst excision and Roux-en-Y hepaticojejunostomy has become a common procedure for pediatric choledochal cyst in many medical centers. With increased familiarity with the laparoscopic anatomy of the biliary tract and advances in minimally invasive techniques, surgeons have ventured further to operate on technically difficult cases such as choledochal cyst that were until recently managed by laparotomy. Our preliminary result shows that laparoscopic excision of choledochal cyst and Roux-en-Y hepaticojejunostomy is effectiveness in pediatric patients. The purpose of this study was to determine the feasible and safe of the laparoscopic excision with Roux-en-Y hepaticojejunostomy, and evaluate the short-term outcomes after treatment for children with choledochal cyst.

METHODS

A prospective study involving 51 pediatric patients diagnosed with choledochal cysts at Hue Central Hospital from June 2012 to December 2017. All patients underwent laparoscopic choledochal cyst excision and Roux-en-Y hepaticojejunostomy. All procedures were performed by the same surgery team. This study was approved by the ethics committee review board of our hospital.

The variables investigated were demographic information of all patients, operative details and outcomes such as operation time, intra-operative blood transfusion, post-operative time to first flatus and post-operative hospital stay, and post-operative complications.

Operative technique

The procedure of laparoscopic choledochal cyst excision is summarized below:

- Under general anesthesia, the patient was intubated and placed in reverse Trendelenburg position.
- Four-site procedure was used as the trocars were located at middle of the umbilicus, right hypochondrium, right side of the abdomen, and left hypochondrium, respectively.
- A monopolar electrocautery hook was used to dissect the choledochal cyst and the gallbladder. The cyst was dissected down to the distal tapered end of the common bile duct, and it was then ligated. The upper part of the cyst was further dissected up to the common hepatic duct and then removed at this level. When severe adhesion around the cyst was encountered, bipolar coagulation was used for dissecting.
- A Roux-en-Y anastomosis was constructed by exteriorization of the small bowel via the enlarged umbilical trocar port. A retrocolic end-to-side hepaticejunostomy was carried out laparoscopically. To minimize the biliary contamination of peritoneum, our procedure was modified later in the series by completing the jejunojejunostomy before the cyst excision.
- Draining tube was indicated only in selected cases.
- When common hepatic duct stenosis was encountered in the Todani-IVa type cases, the stenosis was resected or a ductoplasty was performed by a longitudinal incision on the anterior wall and followed by additional cholangioenterostomy.

Postoperative management and follow-up of patients

Patients usually started a liquid diet on postoperative day 1. Jackson-Pratt drains were removed if ultrasound that were performed on postoperative day 4 showed no evidence of abnormal fluid collection. Patients revisited the outpatient department 2 weeks after discharge and were followed up at 3 months to monitor postoperative complications. For follow-up, a routine complete blood count, liver function test, and ultrasound or CT were performed to evaluate complications, such as pancreatitis, cholangitis, choledocholithiasis, or malignancy.

Clinical outcome was determined according to the Terblanche classification: grade I, no biliary symptoms; grade II, transitory symptoms and no current symptoms; grade III, biliary symptoms requiring medical therapy; and grade IV, recurrent biliary symptoms requiring correction or related to death. Terblanche class IV constituted a poor result. Terblanche I, II, and III constituted a clinical success with excellent, good, and fair results, respectively.

Data analysis

For a descriptive analysis, the frequency or the mean and standard deviation were calculated for each variable. For other continuous variables, independent sample t-tests were applied to compare the data from the children and adult groups. Their respective p values and corresponding confidence intervals were provided by SPSS Version 18.0 (SPSS Inc., Chicago, Illinois, USA). The statistical significance was set at p<0.05.

RESULTS

Forty-one patients were females and 10 were males. The mean age at the time of surgery was 3.55 years (range, 2.5 months–15 years). The mean operative time was 214.7±67.95 minutes (range, 100–360 minutes), including the time for intraoperative cholangiography. The patient characteristics and the operative features were seen in Table 1.

Table 2 shows the surgical outcomes of laparoscopic choledochal cyst excision and Roux-en-Y hepaticejunostomy. There were two children requiring blood transfusion with the total volume of packed red blood cells of 125.0±35.36 ml. Time to first flatus was 40.35±28.55 hours in average. The mean time to
drain removal was 2.89±1.02 days. Mean postoperative hospital stay was 9.31±3.43 days. 6/51 cases having early complications, including 2 cases of pancreatitis and 4 cases of bile leakage. Conservative treatment was initially implemented which resulted in complete resolution in 5 cases. Re-operative was finally required in 1 case with persistent bile leakage. Most of cases were classified as good after 10 days to 3 months of follow-up.

DISCUSSION

Choledochal cyst is a rare congenital anomaly of the biliary system that commonly affects the Asian population. The estimated incidence of choledochal cyst and anomalous pancreaticobiliary ductal union is 0.3% and 4.1%, respectively, according to a large, multicenter study. The clinical presentation of choledochal cyst differs from children to adults. In adults, this disease entity can manifest cholangitis, pancreatitis, choledocholithiasis, or biliary malignancy, such as cholangiocarcinoma or gallbladder cancer. Complete excision of the cyst is mandatory because of the risk of developing complications or malignancies.

With growing interest in cosmetics, laparoscopic approaches in hepatobiliary surgery have become inevitable. Laparoscopic hepaticojejunostomy anastomosis still remains one of the most sophisticated and challenging surgeries to date. Since the first report of laparoscopic choledochal cyst excision in 1995, studies regarding this approach have reported that laparoscopic surgery is safe and feasible in the treatment of choledochal cysts.

Choledochal cyst is characterized by its remarkably higher incidence in the female patients together with the regional preference. In this study also, we found more cases of female patients, the female/male ratio in our study was 4.0/1. This is similar to other studies. Since choledochal cyst is more common in female, the aesthetic advantages of laparoscopic procedure are more relevant. Patient’s age ranged from 2.5 months to 15 years (Table 1). The mean age was 3.55 years. The results of our study were similar to other studies. Since the first report of choledochal cyst excision is bleeding requiring intraoperative blood transfusion. Liem et al reported four cases with bleeding requiring intraoperative blood transfusion, three cases with transection of both hepatic ducts and one case with right hepatic duct perforation. Tang et al noted 8 cases requiring intraoperative blood transfusion. One of the complications of laparoscopic choledochal cyst excision is bleeding requiring intraoperative blood transfusion. Liem et al reported four cases with bleeding requiring intraoperative blood transfusion, three cases with transection of both hepatic ducts and one case with right hepatic duct perforation. Tang et al noted 8 cases requiring intraoperative blood transfusion. Regard the early postoperative complications, we noted 6/51 cases having early complications, including 2 cases of pancreatitis and 4 cases of bile leakage. Conservative treatment was initially implemented which resulted in complete resolution in 5 cases. Reoperative was finally required in 1 cases with persistent bile leakage. Reoperative was finally required in 1 cases with
persistent bile leakage. Ono et al reported liver dysfunction, dilatation of intrahepatic bile ducts, recurrent abdominal pain, and biliary tract malignancy as long-term complications after choledochal cyst excision and hepaticojejunostomy.18 The laparoscopic approach can magnify the operative view, which may assist in dissecting the whole choledochal cyst without a remnant duct, and in anastomosis. Liuming et al reported 1 case of postoperative bile leakage in a study of 39 patients.19 In a study of Acker et al the rate of bile leakage was 1.6%. Pancreatitis was a relatively rare postoperative complication after choledochal cyst excision. Preoperative pancreatitis might be an important risk factor predisposing the patient to postoperative pancreatitis.30 Compared to other studies, the rates of early complications of our study was low.

Several tips were suggested by some authors to reduce the rate of bile leakage. Firstly, electrical dissection should not be overused and over-dissecting the anterior wall of common hepatic duct should also be avoided. Secondly, good laparoscopic suture technique should be practiced. Thirdly, bowel loop with good arterial arcade with sufficient length should be chosen to construct a tension free anastomosis. Finally, the anastomosis should be carefully checked before the end of the operation. Other reported complication including incisional fluid collection, pancreatic fistulas and early adhesive intestinal obstruction was not noted in our study.

Our study contains some limitations. Firstly, the sample size was small and the follow-up period was short (within 3 months). Secondly, there was no control group to compare such as open surgery to see the efficiency of laparoscopic choledochal cyst excision and Roux-en-Y hepaticojejunostomy in children.

CONCLUSION

Laparoscopic choledochal cyst excision and Roux-en-Y hepaticojejunostomy was feasible and safe in children. It could significantly improve in terms of operative time, overall postoperative complication rate, and the length of hospital stay. The short-term outcomes were good in most cases.

ACKNOWLEDGEMENTS

The authors are grateful to Prof. Pham Nhu Hiep – director of Hue Central Hospital; physicians, administrative staff at Department of Pediatric and Abdominal Emergency Surgery for allowing us to undertake this research.
